

SENSITIVITY ANALYSIS EXCLUDING THE AMBIGUOUS FACTUALITY-HALLUCINATION ITEM

A post hoc inspection identified one factuality-hallucination item (`orig_id` = 10) for which the designated answer key was potentially ambiguous. As a sensitivity check, we repeated the trial-level analyses after excluding trial-level rows from this item after applying the same protocol and familiarity filters used in the main analyses (`protocol_ok` = 1 and `familiarity` = 0).

The exclusion removed 23 observations, all of which belonged to second-half factuality-hallucination trials. The participant-level pre/post questionnaire analyses were not trial-specific and were therefore unchanged; the first-hallucination trust-loss analysis also remained unchanged.

TABLE I
SUMMARY OF THE SENSITIVITY ANALYSIS EXCLUDING `orig_id` = 10.

Check	Original analysis	Excluding <code>orig_id</code> = 10	Interpretation
Trial-level rows	227 valid unfamiliar trials; 112 second-half trials	204 valid unfamiliar trials; 89 second-half trials	23 rows excluded; all were second-half factuality-hallucination trials.
Phase model	$F(1, 195.310) = 73.561$, $p < .001$	$F(1, 175.891) = 68.238$, $p < .001$	Trust remained lower in the second half of the task.
Second-half response-type model	$F(2, 72.171) = 19.082$, $p < .001$	$F(2, 52.342) = 14.879$, $p < .001$	The response-type effect remained significant.
Embodiment $\times$ response type	$p = .118$	$p = .172$	The interaction remained non-significant.

Factuality-hallucination EMM changed only slightly (5.337 to 5.423). Correct trials remained higher than both hallucination types, and factuality and faithfulness hallucinations still did not differ significantly ($p = 1.000$).

Note. The Text-only response-type simple effect changed from $p = .020$ to $p = .053$, but this simple effect was not a main reported conclusion and does not affect the interpretation of RQ1 or RQ2.
